

Jan Samadhan AI

An Intelligent Agent for Government Grievance Redressal — Classification, Prioritisation & Department Routing

Jan Samadhan AI is an intelligent agent that reads citizen grievances submitted through a public portal, automatically classifies them into the correct government department, scores their urgency into an explainable priority level, and routes them to the responsible officer with an SLA deadline. It combines a citizen-facing web portal, a rule-and-ML priority engine, and an escalation workflow so that genuinely urgent complaints reach the right official quickly while routine ones are handled without human bottlenecks.

2. PEAS Table

Component	Description
Performance Measure	Correct department-routing accuracy; correct priority/urgency classification (low false negatives on life-threatening or high-risk complaints); low false-positive escalation rate; time taken from submission to routing; number of duplicate tickets correctly merged; percentage of complaints resolved within SLA; citizen satisfaction rating; officer trust/adoption of the system.
Environment	The public grievance portal (web/SMS), citizens submitting complaints from anywhere in the state, government departments and their officers, the escalation authority ladder up to the District Collector level, and the backend database of past complaints and resolutions.
Actuators	Department assignment written to the ticket; priority level and SLA deadline set; tracking-ID and status page shown to the citizen; SMS/email/dashboard alert sent to the responsible officer; duplicate-complaint linking; automatic SLA-breach escalation to the next rung of authority.
Sensors	Free-text complaint box on the web portal (and SMS gateway); citizen-entered ward/locality; optional photo upload; login/anonymous-ID metadata; repeat-submission signal; officer status updates and admin corrections fed back into the system.

3. Environment Properties

Property	Classification	Why
Observability	Partially observable	The agent only sees the citizen's typed description and metadata; the real on-ground situation, its severity, and whether the officer genuinely resolved it are never fully known.
Determinism	Stochastic	The same wording can describe very different real situations, and classifier confidence is probabilistic rather than certain, so outcomes are not guaranteed by the rules alone.
Episodic vs Sequential	Sequential	Past complaints from the same citizen/locality, duplicate history, and prior escalations all influence how the current complaint is triaged and merged.
Static vs Dynamic	Dynamic	Officer availability, department workload, and SLA clocks keep changing while the agent is reasoning, and the queue is being updated continuously by other citizens.
Discrete vs Continuous	Continuous / Mixed	Priority index (0-1 severity, urgency, frequency and risk scores) is continuous-valued, while department and priority-level outputs are discrete categories.
Single vs Multi-agent	Multi-agent (cooperative)	The citizen, the AI agent, the department officer, and the admin escalation process jointly operate in and influence the same ticket.
Known vs Unknown	Known (rules) with unknown edge cases	Category-department mapping, SLA hours and escalation chains are fully known and encoded, but ambiguous or cross-department complaints are not always fully covered.

4. Rationality Measure

The agent is rational to the extent that, given its percept sequence (complaint text + locality + submission history) and its encoded department/priority knowledge base, it selects the action — classify, score, route, or escalate — that maximises citizen safety and administrative efficiency while minimising wasted officer effort. Concretely, rationality is measured by: (a) zero missed emergencies (no false negatives on life-threatening language such as live wires, fire, or accidents, which trigger a hard safety-override floor), (b) high category-routing accuracy so complaints reach the correct department the first time, (c) a low false-positive critical-priority rate so officers are not overwhelmed, and (d) explainable, auditable decisions that an officer or admin can verify and

correct, since a rational agent here must act correctly under uncertainty, not merely follow rules blindly.

5. Innovation Point

Unlike a generic keyword-matching ticketing system, Jan Samadhan AI blends a learned TF-IDF + Logistic Regression classifier with a transparent, weighted priority index (severity, urgency, frequency, risk) plus hard safety overrides, so life-threatening complaints can never be silently under-triaged. Its duplicate-detection layer merges repeat reports of the same incident instead of creating duplicate tickets, and if the ML service is ever unreachable the backend falls back to a keyword classifier so a citizen's complaint is never lost — only flagged for human review.

6. Diagram — Agent Architecture

Fig 1. Citizen complaint → Agent Program (classification + explainable priority scoring + knowledge base) → Actuator flow (routing, SLA, alerts), with officer and citizen loops, plus escalation feedback for continual refinement.

7. Conclusion

Jan Samadhan AI demonstrates how a modest, explainable, model-based reflex agent with a utility-based priority layer can meaningfully augment government grievance handling without needing a citizen to know which department to approach. By combining a learned classifier with a transparent, rule-audited priority score, it turns free-text complaints into timely, accountable department routing — bringing basic administrative triage intelligence to citizen-facing e-governance.

8. Simulation

A simplified Python simulation (`grievance_agent_simulation.py`, submitted alongside this report) implements the agent as a model-based reflex agent with a utility-based decision layer, mirroring the real ML service's logic (`taxonomy.py` + `features.py`) in the full Jan Samadhan portal:

- `Complaint` – represents one percept bundle: the citizen's free-text description and a repeat-submission flag.
- `generate_sample_complaints()` – stands in for live portal traffic with a fixed set of realistic complaints spanning electricity, water, sanitation, roads, revenue, and health categories.
- `GrievanceTriageAgent._classify_category()` – a simplified keyword-matching classifier (the real service uses a TF-IDF + Logistic Regression model trained on 6,451 labelled complaints, 97.4% held-out accuracy).
- `_lexicon_score()` – scores the complaint text against urgency, severity, frequency, and risk keyword lexicons drawn from the real taxonomy.
- `perceive_and_act()` – computes the explainable priority index ($0.40 \cdot \text{severity} + 0.25 \cdot \text{urgency} + 0.20 \cdot \text{frequency} + 0.15 \cdot \text{risk}$), applies a hard safety override for life-threatening language, and produces a reasoning trace.
- `_decide()` – a utility/threshold function that maps the priority index (plus the safety override) to one of four levels: LOW, MEDIUM, HIGH, or CRITICAL, each carrying its own SLA deadline.
- `run_simulation()` – drives eight simulated complaints, prints each one's category, routed department, priority index, reasoning trace, and final action, then prints a session-level performance summary.

Running the script (`python3 grievance_agent_simulation.py`) generates a detailed report for every simulated complaint, including the citizen's original text, the matched category, the department it was routed to, the computed priority index, the reasoning trace, and the final priority/SLA decision. The simulation validates the core logic of Jan Samadhan AI — explainable, safety-first triage that separates genuinely urgent complaints from routine ones — using the same weighting scheme and safety-override principle as the production ML service.
